IsaSAT: Heuristics and Code Generation

Mathias Fleury, Jasmin Blanchette, Peter Lammich

August 2, 2023

Contents

1 Refinement of Literals **5**
- 1.1 Literals as Natural Numbers . . . 5
  - 1.1.1 Definition . . . 5
  - 1.1.2 Lifting to annotated literals . . . 6
- 1.2 Conflict Clause . . . 6
- 1.3 Atoms with bound . . . 6
- 1.4 Operations with set of atoms. . . . 7
- 1.5 Set of atoms with bound . . . 8
- 1.6 Instantion for code generation . . . 13
  - 1.6.1 Literals as Natural Numbers . . . 13
  - 1.6.2 State Conversion . . . 14
  - 1.6.3 Code Generation . . . 14
- 1.7 Polarities . . . 16
  - 1.7.1 Atom-Of . . . 19

2 The memory representation: Arenas **31**
- 2.1 Status of a clause . . . 32
- 2.2 Definition . . . 33
- 2.3 Separation properties . . . 36
- 2.4 MOP versions of operations . . . 62
  - 2.4.1 Access to literals . . . 62
  - 2.4.2 Swapping of literals . . . 63
  - 2.4.3 Position Saving . . . 63
  - 2.4.4 Clause length . . . 64
- 2.5 Virtual Domain . . . 73
- 2.6 Virtual domain . . . 73
- 2.7 Code Generation . . . 75

3 The memory representation: Manipulation of all clauses **95**

4 Efficient Trail **105**
- 4.1 Types . . . 105
- 4.2 Control Stack . . . 106
- 4.3 Encoding of the reasons . . . 109
- 4.4 Definition of the full trail . . . 110
- 4.5 Code generation . . . 111
  - 4.5.1 Conversion between incomplete and complete mode . . . 111
  - 4.5.2 Level of a literal . . . 111
  - 4.5.3 Current level . . . 112

4.5.4 Polarity . . . 112
4.5.5 Length of the trail . . . 113
4.5.6 Consing elements . . . 113
4.5.7 Setting a new literal . . . 119
4.5.8 Polarity: Defined or Undefined . . . 120
4.5.9 Reasons . . . 120
4.6 Direct access to elements in the trail . . . 122
4.7 Options . . . 128
4.7.1 Definition . . . 128
4.7.2 Refinement . . . 129
4.8 Moving averages . . . 131
4.8.1 Phase saving . . . 132

5 Phase Saving **133**
5.1 Rephasing . . . 133
5.2 Statistics . . . 147
5.3 Information related to restarts . . . 155
5.4 Heuristics . . . 156
5.4.1 Number of clauses . . . 165
5.4.2 Lifting to heuristic level . . . 172
5.4.3 Variable-Move-to-Front . . . 244
5.4.4 Hash for lists . . . 296

6 LBD **297**
6.1 Types and relations . . . 297
6.2 Testing if a level is marked . . . 297
6.3 Marking more levels . . . 298
6.4 Cleaning the marked levels . . . 298
6.5 Extracting the LBD . . . 301

7 Refinement of the Watched Function **305**
7.1 Definition . . . 305
7.2 Operations . . . 305
7.3 Rewatch . . . 306

8 Clauses Encoded as Positions **319**

9 Profiling **331**
9.1 Occurrence lists . . . 412
9.1.1 Abstract Occurrence Lists . . . 412
9.1.2 Concrete Occurrence lists . . . 414
9.2 Clause Marking . . . 418
9.2.1 Abstract Representation . . . 418
9.2.2 Concrete Representation . . . 421
9.3 ACIDS . . . 424
9.3.1 Access Function . . . 433

10 Complete state **437**
10.1 VMTF . . . 437
10.1.1 Conflict . . . 437
10.2 Full state . . . 438
10.3 Lift Operations to State . . . 445
10.4 More theorems . . . 446
10.5 Shared Code Equations . . . 449
10.6 Fast to slow conversion . . . 451
10.6.1 Lifting of Options . . . 464

11 Sorting of clauses **473**

12 Printing information about progress **489**
12.0.1 Print Information for IsaSAT . . . 489

13 VMTF Decision Heuristic **631**
13.1 Code generation for the VMTF decision heuristic and the trail . . . 631
13.2 Bumping . . . 642
13.3 Backtrack level for Restarts . . . 651

14 Propagation: Inner Loop **723**
14.1 Find replacement . . . 723
14.2 Updates . . . 731
14.3 Full inner loop . . . 738
14.4 DRAT proof generation . . . 768

15 Backtrack **773**
15.1 Backtrack with direct extraction of literal if highest level . . . 773

16 Backtrack **781**
16.1 Backtrack with direct extraction of literal if highest level . . . 781
16.2 Backtrack with direct extraction of literal if highest level . . . 833
16.2.1 Access Function . . . 843

17 Initialisation **853**
17.1 Code for the initialisation of the Data Structure . . . 853
17.1.1 Initialisation of the state . . . 853
17.1.2 Parsing . . . 859
17.1.3 Extractions of the atoms in the state . . . 874
17.1.4 Parsing . . . 882
17.1.5 Conversion to normal state . . . 885

18 Propagation Loop And Conflict **985**
18.1 Unit Propagation, Inner Loop . . . 985
18.2 Unit propagation, Outer Loop . . . 985

19 Decide **991**

20 Combining Together: the Other Rules **1007**

21 Combining Together: the Other Rules **1009**

22 Restarts **1029**
22.1 Simplification of binary clauses 1168
22.2 Forward subsumption 1214
22.2.1 Algorithm 1214
22.2.2 Refinement to isasat. 1247

23 Full CDCL with Restarts **1345**

24 Full IsaSAT **1367**
24.1 Correctness Relation 1369
24.2 Refinements of the Whole SAT Solver 1373
24.3 Refinements of the Whole Bounded SAT Solver 1413

25 Code of Full IsaSAT **1443**

Chapter 1

Refinement of Literals

1.1 Literals as Natural Numbers

1.1.1 Definition

lemma *Pos-div2-iff*:
‹*Pos* ((*bb* :: *nat*) *div* 2) = *b* ⟷ *is-pos b* ∧ (*bb* = 2 ∗ *atm-of b* ∨ *bb* = 2 ∗ *atm-of b* + 1)›
by (*cases b*) *auto*
lemma *Neg-div2-iff*:
‹*Neg* ((*bb* :: *nat*) *div* 2) = *b* ⟷ *is-neg b* ∧ (*bb* = 2 ∗ *atm-of b* ∨ *bb* = 2 ∗ *atm-of b* + 1)›
by (*cases b*) *auto*

Modeling *nat literal* via the transformation associating $(2::'a) * n$ or $(2::'a) * n + (1::'a)$ has some advantages over the transformation to positive or negative integers: 0 is not an issue. It is also a bit faster according to Armin Biere.

fun *nat-of-lit* :: ‹*nat literal* ⇒ *nat*› **where**
‹*nat-of-lit* (*Pos L*) = 2∗*L*›
| ‹*nat-of-lit* (*Neg L*) = 2∗*L* + 1›

lemma *nat-of-lit-def*: ‹*nat-of-lit L* = (*if is-pos L then* 2 ∗ *atm-of L else* 2 ∗ *atm-of L* + 1)›
by (*cases L*) *auto*

fun *literal-of-nat* :: ‹*nat* ⇒ *nat literal*› **where**
‹*literal-of-nat n* = (*if even n then Pos* (*n div* 2) *else Neg* (*n div* 2))›

lemma *lit-of-nat-nat-of-lit*[*simp*]: ‹*literal-of-nat* (*nat-of-lit L*) = *L*›
by (*cases L*) *auto*

lemma *nat-of-lit-lit-of-nat*[*simp*]: ‹*nat-of-lit* (*literal-of-nat n*) = *n*›
by *auto*

lemma *atm-of-lit-of-nat*: ‹*atm-of* (*literal-of-nat n*) = *n div* 2›
by *auto*

There is probably a more "closed" form from the following theorem, but it is unclear if that is useful or not.

lemma *uminus-lit-of-nat*:
‹− (*literal-of-nat n*) = (*if even n then literal-of-nat* (*n*+1) *else literal-of-nat* (*n*−1))›
by (*auto elim*!: *oddE*)

lemma *literal-of-nat-literal-of-nat-eq*[*iff*]: ‹*literal-of-nat x* = *literal-of-nat xa* ⟷ *x* = *xa*›

by *auto presburger+*

definition *nat-lit-rel* :: ‹(*nat* × *nat literal*) *set*› **where**
‹*nat-lit-rel* = *br literal-of-nat* (λ-. *True*)›

lemma *ex-literal-of-nat*: ‹∃ *bb*. *b* = *literal-of-nat bb*›
by (*cases b*)
(*auto simp*: *nat-of-lit-def split*: *if-splits*; *presburger*; *fail*)+

1.1.2 Lifting to annotated literals

fun *pair-of-ann-lit* :: ‹('*a*, '*b*) *ann-lit* ⇒ '*a literal* × '*b option*› **where**
‹*pair-of-ann-lit* (*Propagated L D*) = (*L*, *Some D*)›
| ‹*pair-of-ann-lit* (*Decided L*) = (*L*, *None*)›

fun *ann-lit-of-pair* :: ‹'*a literal* × '*b option* ⇒ ('*a*, '*b*) *ann-lit*› **where**
‹*ann-lit-of-pair* (*L*, *Some D*) = *Propagated L D*›
| ‹*ann-lit-of-pair* (*L*, *None*) = *Decided L*›

lemma *ann-lit-of-pair-alt-def*:
‹*ann-lit-of-pair* (*L*, *D*) = (*if D* = *None then Decided L else Propagated L* (*the D*))›
by (*cases D*) *auto*

lemma *ann-lit-of-pair-pair-of-ann-lit*: ‹*ann-lit-of-pair* (*pair-of-ann-lit L*) = *L*›
by (*cases L*) *auto*

lemma *pair-of-ann-lit-ann-lit-of-pair*: ‹*pair-of-ann-lit* (*ann-lit-of-pair L*) = *L*›
by (*cases L*; *cases* ‹*snd L*›) *auto*

lemma *literal-of-neq-eq-nat-of-lit-eq-iff*: ‹*literal-of-nat b* = *L* ⟷ *b* = *nat-of-lit L*›
by (*auto simp del*: *literal-of-nat.simps*)

lemma *nat-of-lit-eq-iff*[*iff*]: ‹*nat-of-lit xa* = *nat-of-lit x* ⟷ *x* = *xa*›
apply (*cases x*; *cases xa*) **by** *auto presburger+*

definition *ann-lit-rel*:: ‹('*a* × *nat*) *set* ⇒ ('*b* × *nat option*) *set* ⇒
(('*a* × '*b*) × (*nat*, *nat*) *ann-lit*) *set*› **where**
ann-lit-rel-internal-def:
‹*ann-lit-rel R R'* = {(*a*, *b*). ∃ *c d*. (*fst a*, *c*) ∈ *R* ∧ (*snd a*, *d*) ∈ *R'* ∧
b = *ann-lit-of-pair* (*literal-of-nat c*, *d*)}›

1.2 Conflict Clause

definition *the-is-empty* **where**
‹*the-is-empty D* = *Multiset.is-empty* (*the D*)›

Chapter 2

The memory representation: Arenas

We implement an "arena" memory representation: This is a flat representation of clauses, where all clauses and their headers are put one after the other. A lot of the work done here could be done automatically by a C compiler (see paragraph on Cadical below).

While this has some advantages from a performance point of view compared to an array of arrays, it allows to emulate pointers to the middle of array with extra information put before the pointer. This is an optimisation that is considered as important (at least according to Armin Biere).

In Cadical, the representation is done that way although it is implicit by putting an array into a structure (and rely on UB behaviour to make sure that the array is "inlined" into the structure). Cadical also uses another trick: the array is but inside a union. This union contains either the clause or a pointer to the new position if it has been moved (during GC-ing). There is no way for us to do so in a type-safe manner that works both for *uint64* and *nat* (unless we know some details of the implementation). For *uint64*, we could use the space used by the headers. However, it is not clear if we want to do do, since the behaviour would change between the two types, making a comparison impossible. This means that half of the blocking literals will be lost (if we iterate over the watch lists) or all (if we iterate over the clauses directly).

The order in memory is in the following order:

1. the saved position (was optional in cadical too; since sr-19, not optional);
2. the status and LBD;
3. the size;
4. the clause.

Remark that the information can be compressed to reduce the size in memory:

1. the saved position can be skipped for short clauses;
2. the LBD will most of the time be much shorter than a 32-bit integer, so only an approximation can be kept and the remaining bits be reused for the status;

In previous iteration, we had something a bit simpler:

1. the LBD was in a seperate field, allowing to store the complete LBD (which does not matter).

2. the activity was also stored and used for ties. This was beneficial on some problems (including the *eq.atree.braun* problems), but we later decided to remove it to consume less memory. This did not make a difference on the overall benchmark set. For ties, we use a pure MTF-like scheme and keep newer clauses (like CaDiCaL).

In our case, the refinement is done in two steps:

1. First, we refine our clause-mapping to a big list. This list contains the original elements. For type safety, we introduce a datatype that enumerates all possible kind of elements.
2. Then, we refine all these elements to uint32 elements.

In our formalisation, we distinguish active clauses (clauses that are not marked to be deleted) from dead clauses (that have been marked to be deleted but can still be accessed). Any dead clause can be removed from the addressable clauses (*vdom* for virtual domain). Remark that we actually do not need the full virtual domain, just the list of all active position (TODO?).

Remark that in our formalisation, we don't (at least not yet) plan to reuse freed spaces (the predicate about dead clauses must be strengthened to do so). Due to the fact that an arena is very different from an array of clauses, we refine our data structure by hand to the long list instead of introducing refinement rules. This is mostly done because iteration is very different (and it does not change what we had before anyway).

Some technical details: due to the fact that we plan to refine the arena to uint32 and that our clauses can be tautologies, the size does not fit into uint32 (technically, we have the bound *unat32-max + 1*). Therefore, we restrict the clauses to have at least length 2 and we keep *length C − 2* instead of *length C* (same for position saving). If we ever add a preprocessing path that removes tautologies, we could get rid of these two limitations.

To our own surprise, using an arena (without position saving) was exactly as fast as the our former resizable array of arrays. We did not expect this result since:

1. First, we cannot use *uint32* to iterate over clauses anymore (at least no without an additional trick like considering a slice).
2. Second, there is no reason why MLton would not already use the trick for array.

(We assume that there is no gain due the order in which we iterate over clauses, which seems a reasonnable assumption, even when considering than some clauses will subsume the previous one, and therefore, have a high chance to be in the same watch lists).

We can mark clause as used. This trick is used to implement a MTF-like scheme to keep clauses.

2.1 Status of a clause

datatype *clause-status* = *IRRED* | *LEARNED* | *DELETED*

instantiation *clause-status* :: *default*
begin

definition *default-clause-status* **where** ‹*default-clause-status* = *DELETED*›
instance by *standard*

end

2.2 Definition

The following definitions are the offset between the beginning of the clause and the specific headers before the beginning of the clause. Remark that the first offset is not always valid. Also remark that the fields are *before* the actual content of the clause.

definition *POS-SHIFT* :: *nat* **where**
‹*POS-SHIFT* = *3*›

definition *STATUS-SHIFT* :: *nat* **where**
‹*STATUS-SHIFT* = *2*›

abbreviation *LBD-SHIFT* :: *nat* **where**

  ‹clause-slice arena N i ≡ Misc.slice (i − header-size (N∝i)) (i + length(N∝i)) arena›

abbreviation dead-clause-slice where
  ‹dead-clause-slice arena N i ≡ Misc.slice (i − MIN-HEADER-SIZE) i arena›
```

We now can lift the validity of the active and dead clauses to the whole memory and link it the mapping to clauses and the addressable space.

In our first try, the predicated *xarena-active-clause* took the whole arena as parameter. This however turned out to make the proof about updates less modular, since the slicing already takes care to ignore all irrelevant changes.

```
definition valid-arena :: ‹arena ⇒ nat clauses-l ⇒ nat set ⇒ bool› where
  ‹valid-arena arena N vdom ⟷
    (∀ i ∈# dom-m N. i < length arena ∧ i ≥ header-size (N∝i) ∧

Preconditions and Assertions for the refinement

The following lemma expresses the relation between the arena and the clauses and especially shows the preconditions to be able to generate code.

The conditions on *arena-status* are in the direction to simplify proofs: If we would try to go in the opposite direction, we could rewrite ¬ *irred N i* into *arena-status arena i* ≠ *LEARNED*, which is a weaker property.

The inequality on the length are here to enable simp to prove inequalities *Suc 0* < *arena-length arena C* automatically. Normally the arithmetic part can prove it from *2* ≤ *arena-length arena C*, but as this inequality is simplified away, it does not work.

lemma *arena-lifting*:

lemma valid-arena-one-notin-vdomD:
  ‹valid-arena M N vdom ⟹ Suc 0 ∉ vdom›
  using arena-dom-status-iff[of M N vdom 1]
  by auto
```

This is supposed to be used as for assertions. There might be a more "local" way to define it, without the need for an existentially quantified clause set. However, I did not find a definition which was really much more useful and more practical.

```
definition arena-is-valid-clause-idx :: ‹arena ⇒ nat ⇒ bool› where
‹arena-is-valid-clause-idx arena i ⟷
  (∃N vdom. valid-arena arena N vdom ∧ i ∈# dom-m N)›
```

This precondition has weaker preconditions is restricted to extracting the status (the other headers can be extracted but only garbage is returned).

```
definition arena-is-valid-clause-vdom :: ‹arena ⇒ nat ⇒ bool› where
‹arena-is-valid-clause-vdom arena i ⟷
  (∃N vdom. valid-arena arena N vdom ∧ (i ∈ vdom ∨ i ∈# dom-m N))›

lemma SHIFTS-alt-def:
  ‹POS-SHIFT = (Suc (Suc (Suc 0)))›
  ‹STATUS-SHIFT = (Suc (Suc 0))›
  ‹SIZE-SHIFT = Suc 0›
  by (auto simp: SHIFTS-def)

definition arena-is-valid-clause-idx-and-access :: ‹arena ⇒ nat ⇒ nat ⇒ bool› where
‹arena-is-valid-clause-idx-and-access arena i j ⟷
  (∃N vdom. valid-arena arena N vdom ∧ i ∈# dom-m N ∧ j < length (N ∝ i))›
```

This is the precondition for direct memory access: $N\ !\ i$ where $i = j + (j - i)$ instead of $N \propto j\ !\ (i - j)$.

```

Chapter 4

Efficient Trail

Our trail contains several additional information compared to the simple trail:

- the (reversed) trail in an array (i.e., the trail in the same order as presented in "Automated Reasoning");
- the mapping from any *literal* (and not an atom) to its polarity;
- the mapping from a *atom* to its level or reason (in two different arrays);
- the current level of the state;
- the control stack.

We copied the idea from the mapping from a literals to it polarity instead of an atom to its polarity from a comment by Armin Biere in CaDiCal. We only observed a (at best) faint performance increase, but as it seemed slightly faster and does not increase the length of the formalisation, we kept it.
The control stack is the latest addition: it contains the positions of the decisions in the trail. It is mostly to enable fast restarts (since it allows to directly iterate over all decision of the trail), but might also slightly speed up backjumping (since we know how far we are going back in the trail). Remark that the control stack contains is not updated during the backjumping, but only *after* doing it (as we keep only the the beginning of it).

4.1 Types

type-synonym *trail-pol* =
  ‹*nat literal list* × *tri-bool list* × *nat list* × *nat list* × *nat* × *nat list* × *nat*›

definition *get-level-atm* **where**
  ‹*get-level-atm M L* = *get-level M* (*Pos L*)›

definition *polarity-atm* **where**
  ‹*polarity-atm M L* =
    (*if Pos L* ∈ *lits-of-l M then SET-TRUE*
    else if Neg L ∈ *lits-of-l M then SET-FALSE*
    else None)›

definition *defined-atm* :: ‹('*v*, *nat*) *ann-lits* ⇒ '*v* ⇒ *bool*› **where**

‹*defined-atm M L* = *defined-lit M* (*Pos L*)›

abbreviation *undefined-atm* **where**
‹*undefined-atm M L* ≡ ¬*defined-atm M L*›

4.2 Control Stack

inductive *control-stack* **where**
empty:
‹*control-stack* [] []› |
cons-prop:
‹*control-stack cs M* ⟹ *control-stack cs* (*Propagated L C* # *M*)› |
cons-dec:
‹*control-stack cs M* ⟹ *n* = *length M* ⟹ *control-stack* (*cs* @ [*n*]) (*Decided L* # *M*)›

inductive-cases *control-stackE*: ‹*control-stack cs M*›

lemma *control-stack-length-count-dec*:
‹*control-stack cs M* ⟹ *length cs* = *count-decided M*›
by (*induction rule*: *control-stack.induct*) *auto*

lemma *control-stack-le-length-M*:
‹*control-stack cs M* ⟹ *c*∈*set cs* ⟹ *c* < *length M*›
by (*induction rule*: *control-stack.induct*) *auto*

  ASSERT(*atm-of L* < *length reasons*);
  let r = *reasons* ! *atm-of L*;
  RETURN r})›

The version *get-propagation-reason* can return the reason, but does not have to: it can be more suitable for specification (like for the conflict minimisation, where finding the reason is not mandatory).

The following version *always* returns the reasons if there is one. Remark that both functions are linked to the same code (but *get-propagation-reason* can be called first with some additional filtering later).

4.7 Options

We define the options from our SAT solver. Using options has several advantages: it is much easier to change the value (instead of recompiling everything from scratch the complete Isabelle development) and it is easier to change.

We hide the options inside a datatype to make sure Isabelle does not split the the component to make goals even less readable.

4.7.1 Definition

type-synonym *opts-target* = ⟨*3 word*⟩

datatype *opts* =
IsaOptions (*opts-restart*: *bool*)
(*opts-reduce*: *bool*)
(*opts-unbounded-mode*: *bool*)

4.8 Moving averages

definition *EMA-FIXPOINT-SIZE* :: ‹*nat*› **where**
‹*EMA-FIXPOINT-SIZE* = *32*›

We use (at least hopefully) the variant of EMA-14 implemented in Cadical, but with fixed-point calculations (*1* is *1* >> *EMA-FIXPOINT-SIZE*).
Remark that the coefficient β already should take care of the fixed-point conversion of the glue. Otherwise, *value* is wrongly updated.

type-synonym *ema* = ‹*64 word* × *64 word* × *64 word* × *64 word* × *64 word*›

definition *ema-bitshifting* **where**
‹*ema-bitshifting* = (*1* << *EMA-FIXPOINT-SIZE*)›

definition *EMA-MULT-SHIFT* :: ‹*nat*› **where**
‹*EMA-MULT-SHIFT* = *8*›

TODO: some precision is lost here in the difference calculation.

definition (**in** −) *ema-update* :: ‹*nat* ⇒ *ema* ⇒ *ema*› **where**
‹*ema-update* = (λ*lbd* (*value*, α, β, *wait*, *period*).
let lbd = (*of-nat lbd*) ∗ *ema-bitshifting in*
let value = *if lbd* > *value*
then value + ((β >> (*EMA-FIXPOINT-SIZE* − *EMA-MULT-SHIFT*)) ∗ ((*lbd* − *value*) >> *EMA-MULT-SHIFT*))
else value − ((β >> (*EMA-FIXPOINT-SIZE* − *EMA-MULT-SHIFT*)) ∗ ((*value* − *lbd*) >> *EMA-MULT-SHIFT*))
in
let wait = *wait* − *1 in*
if β ≤ α ∨ *wait* > *0 then* (*value*, α, β, *wait*, *period*)
else
let wait = *2* ∗ (*period*+*1*)−*1 in*
let period = *wait in*
let β = β >> *1 in*
let β = *if* β < α *then* α *else* β *in*
(*value*, α, β, *wait*, *period*))›

definition (**in** −) *ema-init* :: ‹*64 word* ⇒ *ema*› **where**

5.2 Statistics

We do some statistics on the run.

NB: the statistics are not proven correct (especially they might overflow), there are just there to look for regressions, do some comparisons (e.g., to conclude that we are propagating slower than the other solvers), or to test different option combinations.

type-synonym *limit* = ‹*64 word* × *64 word*›

The statistics have the following meaning:

1. search information (propagations, conflicts, decision, restarts, reductions, fixed variables, GCs, units since last GC, fixed irredundant clss),
2. binary simplification (binary unit, binary red removed),
3. pure literals (purelit removed, purelit rounds),
4. forward subsumption (forward rounds, forward strengthen, forward subsumed)
5. other: max kept lbd,
6. ticks
7. average lbds
8. heuristics

At first we used a tuple that became longer and longer. We even had statistics bug because we changed the wrong element of the tuple. Therefore, we changed to a structure and kept some free spots.

type-synonym *search-stats* = ‹*64 word* × *64 word* ×*64 word* × *64 word* × *64 word* × *64 word* ×*64 word* × *64 word* × *64 word* × *64 word*›

‹*clss-size-corr N NE UE NEk UEk NS US N0 U0 c* ⟷ *c* = *clss-size N NE UE NEk UEk NS US N0 U0*›

There is no equivalence because of rounding errors. However, we do not care about that in the proofs and we are always safe in IsaSAT.

However, the intro rule are still too dangerous and make it hard to recognize the original goal. Therefore, they are not marked as safe.

This version of the counter is incomplete. It is however useful because we do not need to care about some of the counts during restarts. In particular, it avoids taking care of overflows.

```

It is tempting to remove the *update-x*. However, it leads to more complicated reasoning later: What happens if x is not in the list, but its successor is? Moreover, it is unlikely to really make a big difference (performance-wise).

```

Chapter 6

LBD

LBD (literal block distance) or glue is a measure of usefulness of clauses: It is the number of different levels involved in a clause. This measure has been introduced by Glucose in 2009 (Audemart and Simon).

LBD has also another advantage, explaining why we implemented it even before working on restarts: It can speed the conflict minimisation. Indeed a literal might be redundant only if there is a literal of the same level in the conflict.

The LBD data structure is well-suited to do so: We mark every level that appears in the conflict in a hash-table like data structure.

Remark that we combine the LBD with a MTF scheme.

6.1 Types and relations

type-synonym *lbd* = ‹*bool list*›
type-synonym *lbd-ref* = ‹*nat list* × *nat* × *nat*›

Beside the actual "lookup" table, we also keep the highest level marked so far to unmark all levels faster (but we currently don't save the LBD and have to iterate over the data structure). We also handle growing of the structure by hand instead of using a proper hash-table.

definition *lbd-ref* :: ‹(*lbd-ref* × *lbd*) *set*› **where**
‹*lbd-ref* = {((*lbd*, *stamp*, *m*), *lbd'*).
length lbd' ≤ *Suc* (*Suc* (*unat32-max div 2*)) ∧
m = *length* (*filter id lbd'*) ∧
stamp > *0* ∧
length lbd = *length lbd'* ∧
(∀ *v* ∈ *set lbd*. *v* ≤ *stamp*) ∧
(∀ *i* < *length lbd'*. *lbd'* ! *i* ⟷ *lbd* ! *i* = *stamp*)
}›

6.2 Testing if a level is marked

definition *level-in-lbd* :: ‹*nat* ⇒ *lbd* ⇒ *bool*› **where**
‹*level-in-lbd i* = (λ*lbd*. *i* < *length lbd* ∧ *lbd*!*i*)›

definition *level-in-lbd-ref* :: ‹*nat* ⇒ *lbd-ref* ⇒ *bool*› **where**
‹*level-in-lbd-ref* = (λ*i* (*lbd*, *stamp*, -). *i* < *length-uint32-nat lbd* ∧ *lbd*!*i* = *stamp*)›

lemma *level-in-lbd-ref-level-in-lbd*:

‹(uncurry (RETURN oo level-in-lbd-ref), uncurry (RETURN oo level-in-lbd)) ∈
nat-rel ×$_r$ lbd-ref →$_f$ ⟨bool-rel⟩nres-rel›
by (intro frefI nres-relI) (auto simp: level-in-lbd-ref-def level-in-lbd-def lbd-ref-def)

6.3 Marking more levels

definition list-grow **where**
‹list-grow xs n x = xs @ replicate (n − length xs) x›

definition lbd-write :: ‹lbd ⇒ nat ⇒ lbd› **where**
‹lbd-write = (λlbd i.

Chapter 7

Refinement of the Watched Function

There is not much to say about watch lists since they are arrays of resizeable arrays, which are defined in a separate theory.

However, when replacing the elements in our watch lists from (*nat* × *uint32*) to (*nat* × *uint32* × *bool*) to enable special handling of binary clauses, we got a huge and unexpected slowdown, due to a much higher number of cache misses (roughly 3.5 times as many on a eq.atree.braun.8.unsat.cnf which also took 66s instead of 50s). While toying with the generated ML code, we found out that our version of the tuples with booleans were using 40 bytes instead of 24 previously. Just merging the *uint32* and the *bool* to a single *uint64* was sufficient to get the performance back.

Remark that however, the evaluation of terms like (*2*::*uint64*) ^ *32* was not done automatically and even worse, was redone each time, leading to a complete performance blow-up (75s on my macbook for eq.atree.braun.7.unsat.cnf instead of 7s).

None of the problems appears in the LLVM code.

Chapter 8

Clauses Encoded as Positions

We use represent the conflict in two data structures close to the one used by the most SAT solvers: We keep an array that represent the clause (for efficient iteration on the clause) and a "hash-table" to efficiently test if a literal belongs to the clause.

The first data structure is simply an array to represent the clause. This theory is only about the second data structure. We refine it from the clause (seen as a multiset) in two steps:

1. First, we represent the clause as a "hash-table", where the i-th position indicates *Some True* (respectively *Some False*, *None*) if *Pos i* is present in the clause (respectively *Neg i*, not at all). This allows to represent every not-tautological clause whose literals fits in the underlying array.

We use the first part in two different ways: once for the conflict, where we specialize it to include only information on the atoms and once in the marking structure.

This is the first level of the refinement. We tried a few different definitions (including a direct one, i.e., mapping a position to the inclusion in the set) but the inductive version turned out to the easiest one to use.

Chapter 9

Profiling

For profiling, we don't do anything except calling some C functions to measure time. As for printing, the functions to nothing in the refinement and are only removed from the generated code. The aim is to better understand the behaviour of the generated code and find performance bug.

begin

We refine it to an array of booleans indicating if the atom is present or not. This information is redundant because we already know that a literal can only appear negated compared to the trail.

The first step makes it easier to reason about the clause (since we have the full clause), while the second step should generate (slightly) more efficient code.

Most solvers also merge the underlying array with the array used to cache information for the conflict minimisation (see theory *Watched-Literals.CDCL-Conflict-Minimisation*, where we only test if atoms appear in the clause, not literals).

As far as we know, versat stops at the first refinement (stating that there is no significant overhead, which is probably true, but the second refinement is not much additional work anyhow and we don't have to rely on the ability of the compiler to not represent the option type on booleans as a pointer, which it might be able to or not).

9.1 Occurrence lists

Occurrence lists (in a single watched way) are very similar to watch lists. For simplification purpose, we use occurrence lists and watch lists, but Kissat uses only the latter for memory efficiency.

This file started as an experiment. We attempted to do better than our watch lists because we know and understand a lot more on refinement. This turned out to do really work out as expected however.

There are two ways to achieve the refinement:

- the most abstract requires to know the set of variable. Which means that we have to somehow get it. Which is impossible (some of the information is deleted anyway), but also something we probably should not try to do.

- just use a bound.

What is the conclusion of all that? Well not much, except that full abstraction is hard to get. So we still end up with the concrete data in the isasat state, which I find sad, but I don't see any way to do it better – and no I am no going back to a locale with an upper bound on the literals; been there, done that.

9.1.1 Abstract Occurrence Lists

type-synonym *raw-occurences* = ‹*nat literal* ⇒ *nat list*›

9.2 Clause Marking

Experiment: This should eventually replace the stuff used for the conflicts. Experiment in the current state to see if useful. If it is this should be generalized. However, not clear because distinct, so not really multisets.

Experiment: is keeping the set of variables as sets useful? is the refinement from there on okay (both from doing it and also performance wise)

9.2.2 Concrete Representation

TODO: The mark structure should probably be replaced by our abstract ch-stuff

TODO: the alternative version consists in keeping the multiset, but replacing the atoms by the upper bound. This makes it possible to keep the abstraction (kind of). However, it is very clear what would be the difference.

begin

Instead of using VSIDS (which requires float), we use the more stable ACIDS variant that works simply on integers and does not seem much worse.

We use ACIDS in a practical way, i.e., when the weight reaches the maximum integer, we simply stop incrementing it.

9.3 ACIDS

This is the setup for accessing and modifying the state as an abstract tuple of 4 elements. The construction is kept generic (even if still targetting only our state). There is a lot of copy-paste that would be nice to automate at some point.

We define 3 sort of operations:

1. extracting an element, replacing it by an default element. Modifies the state. The name starts with *exctr*
2. reinserting an element, freeing the current one. Modifies the state. The name starts with *update*
3. in-place reading a value, possibly with pure parameters. Does not modify the state. The name starts with *read*

Complete state

hide-const (**open**) *IsaSAT-VDom.get-aivdom*

hide-const (**open**) *NEMonad.ASSERT NEMonad.RETURN NEMonad.SPEC*

We here define the last step of our refinement: the step with all the heuristics and fully deterministic code.

After the result of benchmarking, we concluded that the use of *nat* leads to worse performance than using *sint64*. As, however, the later is not complete, we do so with a switch: as long as it fits, we use the faster (called 'bounded') version. After that we switch to the 'unbounded' version (which is still bounded by memory anyhow) if we generate Standard ML code.

We have successfully killed all natural numbers when generating LLVM. However, the LLVM binding does not have a binding to GMP integers.

Chapter 11

Sorting of clauses

We use the sort function developped by Peter Lammich.

For the ordering, we prefer low lbds. If equal we take lower size. Then for tie, clauses derived later are preferred because they are not redundant. The last condition ensures that we do not depend on the order of the clauses in the array.

Chapter 12

Printing information about progress

We provide a function to print some information about the state. This is mostly meant to ease extracting statistics and printing information during the run. Remark that this function is basically an FFI (to follow Andreas Lochbihler words) and is not unsafe (since printing has not side effects), but we do not need any correctness theorems.

However, it seems that the PolyML as targeted by *export-code checking* does not support that print function. Therefore, we cannot provide the code printing equations by default.

For the LLVM version code equations are not supported and hence we replace the function by hand.

hide-const (**open**) *NEMonad.ASSERT NEMonad.RETURN*

This is the setup for accessing and modifying the state as an abstract tuple of 15 elements. The construction is kept generic (even if still targetting only our state). There is a lot of copy-paste that would be nice to automate at some point.

We define 3 sort of operations:

1. extracting an element, replacing it by an default element. Modifies the state. The name starts with *exctr*
2. reinserting an element, freeing the current one. Modifies the state. The name starts with *update*
3. in-place reading a value, possibly with pure parameters. Does not modify the state. The name starts with *read*

This is the setup for accessing and modifying the state. The construction is kept generic (even if still targetting only our state). There is a lot of copy-paste that would be nice to automate at some point.

We define 3 sort of operations:

1. extracting an element, replacing it by an default element. Modifies the state. The name starts with *exctr*
2. reinserting an element, freeing the current one. Modifies the state. The name starts with *update*
3. in-place reading a value, possibly with pure parameters. Does not modify the state. The name starts with *read*

This is the setup for accessing and modifying the state as an abstract tuple of 15 elements. The construction is kept generic (even if still targetting only our state). There is a lot of copy-paste that would be nice to automate at some point.

We define 3 sort of operations:

1. extracting an element, replacing it by an default element. Modifies the state. The name starts with *exctr*
2. reinserting an element, freeing the current one. Modifies the state. The name starts with *update*
3. in-place reading a value, possibly with pure parameters. Does not modify the state. The name starts with *read*

Chapter 17

Initialisation

17.1 Code for the initialisation of the Data Structure

The initialisation is done in three different steps:

1. First, we extract all the atoms that appear in the problem and initialise the state with empty values. This part is called *initialisation* below.
2. Then, we go over all clauses and insert them in our memory module. We call this phase *parsing*.
3. Finally, we calculate the watch list.

Splitting the second from the third step makes it easier to add preprocessing and more important to add a bounded mode.

17.1.1 Initialisation of the state

The initialisation relation is stricter in the sense that it already includes the relation of atom inclusion.

Remark that we replace $D = None \longrightarrow j \leq length\ M$ by $j \leq length\ M$: this simplifies the proofs and does not make a difference in the generated code, since there are no conflict analysis at that level anyway.

KILL duplicates below, but difference: vmtf vs vmtf_init watch list vs no WL OC vs non-OC

```

This is the setup for accessing and modifying the state as an abstract tuple of 15 elements. The construction is kept generic (even if still targetting only our state). There is a lot of copy-paste that would be nice to automate at some point.

We define 3 sort of operations:

1. extracting an element, replacing it by an default element. Modifies the state. The name starts with *exctr*
2. reinserting an element, freeing the current one. Modifies the state. The name starts with *update*
3. in-place reading a value, possibly with pure parameters. Does not modify the state. The name starts with *read*

This is a list of comments (how does it work for glucose and cadical) to prepare the future refinement:

1. Reduction

   - every 2000+300*n (rougly since inprocessing changes the real number, cadical) (split over initialisation file); don't restart if level < 2 or if the level is less than the fast average

- curRestart * nbclausesbeforereduce; curRestart = (conflicts / nbclausesbeforereduce) + 1 (glucose)

2. Killed

   - half of the clauses that **can** be deleted (i.e., not used since last restart), not strictly LBD, but a probability of being useful.
   - half of the clauses

3. Restarts:

   - EMA-14, aka restart if enough clauses and slow_glue_avg * opts.restartmargin > fast_glue (file ema.cpp)
   - (lbdQueue.getavg() * K) > (sumLBD / conflictsRestarts), *conflictsRestarts > LOWER-BOUND-FO*
     && *lbdQueue.isvalid*() && *trail.size*() > *R* ∗ *trailQueue.getavg*()

22.1 Simplification of binary clauses

Special handling of binary clauses is required to avoid special cases of units in the general forward subsumption algorithm (which, as of writing, does not exist).

22.2 Forward subsumption

22.2.1 Algorithm

We first refine the algorithm to use occurence lists, while keeping as many things as possible abstract (like the candidate selection or the selection of the literal with the least number of occurrences). We also include the marking structure (at least abstractly, because why not)

For simplicity, we keep the occurrence list outside of the state (unlike the current solver where this is part of the state.)

definition *valid-occs* **where** ‹*valid-occs occs vdom* ⟷ *cocc-content-set occs* ⊆ *set* (*get-vdom-aivdom vdom*) ∧
distinct-mset (*cocc-content occs*)›

This version is equivalent to *twl-st-heur-restart*, without any information on the occurrence list.

Chapter 24

Full IsaSAT

We now combine all the previous definitions to prove correctness of the complete SAT solver:

1. We initialise the arena part of the state;
2. Then depending on the options and the number of clauses, we either use the bounded version or the unbounded version. Once have if decided which one, we initiale the watch lists;
3. After that, we can run the CDCL part of the SAT solver;
4. Finally, we extract the trail from the state.

   Remark that the statistics and the options are unchecked: the number of propagations might overflows (but they do not impact the correctness of the whole solver). Similar restriction applies on the options: setting the options might not do what you expect to happen, but the result will still be correct.

24.1 Correctness Relation

We cannot use *cdcl-twl-stgy-restart* since we do not always end in a final state for *cdcl-twl-stgy*.

abbreviation *conclusive-TWL-run-bounded* **where**
‹*conclusive-TWL-run-bounded S* ≡ *partial-conclusive-TWL-run S*›

Before introducing the pragmatic CDCL version, we expressed the specification all the level up to Weidenbach's CDCL, but now we stop at the pragmatic CDCL. Technically, we could actually skip the part on the calculus and simply use the conclusive part (no conflict and model, conflict and unsat), but this version is nicer on paper to highlight the refinement approach.

```

The setup to transmit the version is a bit complicated, because Isabelle does not support direct export of string literals. Therefore, we actually convert the version to an array chars (more precisely, of machine words – ended with 0) that can be read and printed by the C layer. Note the conversion must be automatic, because the version depends on the underlying git repository, hence the call to auto.

```
function array-of-version where
  ‹array-of-version i str arr =
    (if i ≥ length str then arr
    else array-of-version (i+1) str (arr[i := str ! i]))›
  by pat-completeness auto
termination
  apply (relation ‹measure (λ(i,str, arr). length str − i)›)
  apply auto
  done
```

Using this as version number makes our work on the cluster easier and makes the version checking slightly easier (because the git hash is never up-to-date).

```
definition internal-version :: ‹string› where ‹internal-version = ''0i''›
```
